(54) Title: METHOD FOR DISPLAYING IMAGES ON A DISPLAY DEVICE, AS WELL AS A DISPLAY DEVICE USED THEREFOR

(57) Abstract

The invention concerns a method for displaying images on a display device, characterised in that use is made of a display device (1) comprising at least a general processing unit (2), a display (3) consisting of several display units (4) and an individual processing unit (5) per display unit (4), whereby, in order to display the images, data concerning the image to be displayed are transmitted from the general processing unit (2) to the individual processing units (5) in the form of a data stream (11), in that there is a control communication between the general processing unit (2) and each of the individual processing units (5) in the form of control signals (13), and in that data from the data stream (11) are collected at every individual processing unit (5) as a function of the control signals (13) transmitted to the individual processing units (5). It also concerns a device consisting of a general processing unit (2) and serially coupled individual processing units (5).

Method for displaying images on a display device, as well
as a display device used therefor.

5

The present invention concerns a method for displaying images on a display device, as well as a display device for realising this method.

10 In particular, the invention concerns display devices comprising a display which consists of several display units, whereby these display units are driven by means of a general processing unit, as well as by means of individual processing units per display unit.

15

In particular, it concerns display devices which make it possible to display images on a large image surface.

The invention is particularly meant for display devices
20 comprising display units whereby the image is reproduced by means of what are called LED's (Light Emitting Diodes).

It is known that an LED wall can so to say be built in this manner. It is also known that, by building the LED wall
25 from groups of LED's of different colours, in particular red, blue and green, by appropriately adjusting the intensity of the different LED's, it is possible to obtain various global colour effects. Also, by means of an appropriate control of the LED's, it is possible to
30 reproduce moving images in colour, for example video images, on the LED wall.

Such display devices can be used for different purposes, for example for displaying images in stadiums, information

and/or publicity in public buildings, such as for example airports, stations, etc.

5 A display device with active modules is known from US 5.523.769. Data are exchanged here between a general processing unit and one central, individual processing unit, which further communicates with the other individual processing units. The different processing units can also communicate among themselves.

10

This known device is disadvantageous in that a large number of mutual data exchanges are required, so that the system is very restricted as far as calculation possibilities are concerned.

15

The invention aims a method for representing images on a display device of the above-mentioned type, whereby this method allows for a smoother data processing than according to the methods known until now.

20

In the first place, the method of the invention is designed for LED screens, but it can also be applied in a more general way in other display devices, such as CRT projectors and the like.

25

To this aim, the invention concerns a method for displaying images on a display device, characterised in that use is made of a display device comprising at least a general processing unit, a display consisting of several display
30 units and an individual processing unit per display unit, whereby, in order to display the images, data concerning the image to be displayed are transmitted from the general processing unit to the individual processing units in the form of a data stream, in that there is a control
35 communication between the general processing unit and each

of the individual processing units in the form of control signals, and in that data from the data stream are collected at every individual processing unit as a function of the control signals transmitted to the individual processing units.

As the data stream is offered to each of the individual processing units on the one hand, and there is a control communication on the basis of which the individual processing units are driven on the other hand, one obtains that every display unit can work independently of the other ones, requiring no communication with a central individual processing unit. As no mutual data exchange is required between the individual processing units, there will be less data transmission, making more calculation time and calculation capacity available for processing the signals in the individual processing units.

Use is preferably made of display units which are serially coupled. As a result of this, the total display can be easily composed in any size whatsoever, without a large number of electric connections being required on the back side of the display.

As already mentioned, use is preferably made here of display units consisting of LED panels.

According to the most preferred embodiment, a distributed signal processing will be provided for according to the invention between the general processing unit on the one hand and the individual processing units on the other hand. This implies that a number of calculations are made in the general processing unit, whereas a number of other calculations are made in each of the individual processing units. This requires less data exchange between the

general processing unit and the individual processing units for the drive, making calculation time available in the general processing unit, as well as transmission time for data via the data line between the general processing unit and the individual processing units which can then be used for a refined transmission of data for displaying the image.

The invention also concerns a display device for realising the above-mentioned method, characterised in that it consists at least of a general processing unit; a display consisting of several display units; an individual processing unit per display unit; means which transmit at least data concerning the image to be displayed transmitted from the general processing unit to the individual processing units in the form of a data stream; means providing for a control communication between the general processing unit and each of the individual processing units in the form of control signals; and, per individual processing unit, means which collect data from the data stream as a function of the transmitted control signals for further processing and display.

In order to better explain the characteristics of the invention, the following preferred embodiment according to the invention is described as an example only without being limitative in any way, with reference to the accompanying drawings, in which:

figure 1 schematically represents a display device according to the invention;
figure 2 represents a model of the display device in figure 1 in perspective;
figure 3 represents the part which is indicated by F3 in figure 2 to a larger scale;

figure 4 represents the back side of the module from figure 2 in perspective;

figure 5 represents the display device in the form of a block diagram;

5 figure 6 represents a number of histograms with reference to images to be displayed;

figure 7 schematically represents a special image geometry.

10 As represented in figure 1, the display device 1 according to the invention mainly consists of a general processing unit 2 and a display 3 consisting of a screen which is composed of several display units 4, whereby every display unit 4 is equipped with an individual processing unit 5.

15 The general processing unit 2, also called digitizer or video engine, consists of an appliance which transforms image signals, either coming from an external source or from an internal source, such as a built-in video player,
20 into digitised signals which are suitable for the reproduction of the image on the display 3.

As represented in figures 2 to 4, the display units 4 consist of tile-shaped modules which, as represented in
25 figure 1, can be assembled by attaching them on an appropriate supporting structure, for example a frame 6.

The modules are preferably fastened in the frame 6 in a detachable manner, for example by making use of fastening
30 elements 7, as represented in figure 4, with which the modules can be snapped in the frame 6.

The image side 8 of the display units 4 is equipped with luminous elements, in particular LED's (Light Emitting
35 Diodes), which are indicated hereafter in a general manner

with the reference 9, but which are indicated with the references 9A to 9E when represented in detail.

The LED's 9A and 9E are red for example, whereas the LED's
5 9B and 9D are green and the LED's 9C are blue. By
controlling the respective LED's 9A-9E and by thus making
the different colours illuminate with different
intensities, it is possible to realise any colour
whatsoever when seen from a distance. Every set of LED's 9
10 hereby forms a pixel of the images to be formed. It should
be noted that such a pixel can be composed in different
ways, of three colours or of a combination of different
groups of LED's 9. Thus, for example, the LED's 9A-9B-9C
form a group of basic colours with which all colours can be
15 formed. The same goes for the LED's 9B-9C-9E as well as
for 9D-9C-9E and 9A-9C-9D.

The invention is special in that the display device 1, as
is schematically represented in figure 5, is equipped with
20 means 10 which at least transmit data concerning the image
to be displayed transmitted from the general processing
unit 2 to the individual processing units 5 in the form of
a data stream 11; means 12 providing for a control
communication between the general processing unit 2 and
25 each of the individual processing units 5 in the form of
control signals 13; and, per individual processing unit 5,
means 14 which collect data from the data stream 11 as a
function of the transmitted control signals 13 for further
processing and display on the image surface, in this case
30 the LED panel, of the display unit 4 concerned.

It should be noted that the data stream 11 and the control
signals 13 are only represented schematically in the
diagram of figure 5 and that, in reality, the data stream
35 11 and the control signals 13 are not necessarily carried

via two different data lines. The data stream 11 and the control signals 13 may consist of a single pulse train in which certain intervals are reserved for the data stream 11 and other intervals are reserved for the control signals 13.

For practical reasons, however, it may be necessary to make different connections between the individual processing units 5, for example in the case where a separate data processing is provided for the different colours, for the control of the red, green and blue LED's 9 respectively, whereby it is transmitted separately per colour to the processing units 5.

Thanks to the design according to figure 5, however, it is possible to use a restricted number of electric connections between the successive display units 4, and they can be coupled serially by means of a number of electric cables 15-16, in particular twisted pairs, which are provided with multipolar connectors 17 which can be plugged in the back side of the processing units 5.

According to a special aspect of the invention, a distributed signal processing is provided for between the general processing unit 2 on the one hand and the individual processing units 5 on the other hand. This implies that a number of data are processed and calculated in the general processing unit 2, whereas a number of other data are processed and calculated in each of the individual processing units 5.

This distributed signal processing can be carried out at different levels.

According to a first aspect, a distributed signal processing of the signals related to the colour rendering is provided for, in other words a distributed colour processing. Also a distributed signal processing related
5 to the brightness and/or contrast can hereby be provided for.

In particular, one or several adjustments are made at the general processing unit 2 related to one or several of the
10 following possibilities:

- image stabilisation and/or noise suppression;
- tracking of the illumination of the image, in other words 'luminance tracking', whereby certain values
15 of the luminance are included;
- histogram equalisation as a function of the entire image to be displayed;
- observing of what is called cue flash and acting appropriately in case of such a cue flash;
- 20 - reduction of the image in relation to the original input image in the horizontal and/or vertical direction.

This implies that the noise suppression is done in a
25 general manner for the entire image display.

Luminance tracking implies determining for example a fixed relation between the different colours beneath a certain luminance before the signals concerned are transmitted to
30 the individual processing units 5.

By histogram equalisation is meant that a histogram of the entire image content is made and that an evaluation is subsequently made and, if necessary, corrections will be

made as a function thereof before the data stream 11 is transmitted to the processing units 5.

By way of illustration, figure 6 represents different curves which can be found in a histogram. H hereby represents the luminance value and I the number of times such values occur in this image. The curves represent all the pixels of the image.

10 In the case of an image which is generally rather grey, a curve A is obtained, a bright image produces the curve B and a dark image the curve C.

As a function of the nature of the curve, either curve A, B or C, a correction can thus be made. One possibility is that, when signals are observed indicating that the image is dark (curve C), the data stream 11 is adjusted such that the darkness is stressed, whereas when signals are observed indicating that the image is bright (curve B), the data stream 11 is adjusted such that the brightness is stressed. In case of curve A, for example, no correction is made.

The adjustments resulting from the evaluation of the histogram can also be linked to time. This implies that also alterations in the histogram for each of the successive images are detected and taken into account. In case of slow alterations, alterations in the output signal will be made less quickly, as a result of which is obtained a stabilisation effect.

30 What is called a cue flash is a sudden alteration of the entire image content, in other words a sudden change in the displayed image. It is clear that, at such a moment, the alteration should not be ignored. A detection of the cue flash allows for appropriate action at that moment.

In order to obtain a distributed signal processing, one or several individual adjustments are made at the individual processing units 5 as well. In particular, these adjustments concern one or several of the following possibilities:

- adjustment of the colour co-ordinates;
- adjustment of the brightness;
- 10 - adjustment of the contrast;
- corrective adjustment as a function of the temperature and/or age of the display unit 4;
- adjustment of the transfer functions RGB (red, yellow, blue);
- 15 - enlargement of the incoming video signal in the horizontal and/or vertical direction.

A number of these items will be illustrated in greater detail hereafter.

20

By colour co-ordinates are meant the co-ordinates in the chromaticity diagram. These co-ordinates determine what colour is visually observed, and they depend on several factors. Thus, for example they are linked to the age of the display unit 4, such that the adjustment must be made individually. However, the adjustment contributes to the general smoothness and uniformity of the colour reproduction in the image.

30 In order to adjust and improve the contrast, different modes are applied in the individual processing units 5, whereby the linear connection between the input signal and the output signal is adjusted towards a non-linear connection, whereby for example dark signals are further

reduced in order to make sure that the LED's 9 remain switched off in case of signals indicating that there is a very dark image part, whereas for example signals indicating that there is a bright image, are reinforced.

5

Thus can be obtained among others that when the viewer is situated close to the display 3, the dark passages will indeed be perceived as being dark, and any annoying flashing of the LED's 9 which can be perceived from nearby is excluded.

10

In particular, a dynamic sample weight distribution is applied above, whereby the individual processing units 5 are informed via the control signals 13 of what curve should be followed during the transformation of the linear course into the non-linear course, depending on the aimed effect.

15

This technique allows for a refined contrast rendering without requiring a large number of contrast level differences in the signal of the general processing unit 2 towards the individual processing units 5. By using different curves, it is possible to create different results, and transmitting a restricted signal from the general processing unit 2 to the individual processing units 5 will suffice to indicate to the latter what curve should be followed.

20

25

By providing for a corrective adjustment as a function of temperature and/or age per display unit 4, and thus also per individual processing unit 5, also other influences of temperature and/or age known as such are separately dealt with, and on condition that there is an appropriate control, differences between the displayed image in each of the display units 4 are excluded. Thus, it is possible to

30

35

remove display units 4 from the display 3 and to replace them at any time, without any disadvantages. It is also possible to build a display 3 of any size whatsoever, even when it contains display units 4 which have been in use for
5 a shorter time than a number of the other display units 4. By age should in this case mainly be understood the total time during which a display unit 4 has been switched on.

The temperature correction offers the advantage that mutual
10 deviations resulting from temperature differences, irrespective of the cause of these temperature differences, are excluded. Said temperature differences may occur for example when, for a longer length of time, only a part of the display 3 is driven so as to form an image, whereas
15 from a certain moment on, the entire display 3 is used. Consequently, the display units 4 which have not been in use until then will not function at operating temperature, and an adjustment because of the temperature differences is advisable.

20

According to another aspect of the invention, also a distributed signal processing of the signals related to the image display, in other words a distributed image processing, is provided for.

25

An example of such distributed image processing consists in that a distributed signal processing is provided for which makes sure that, both at the general processing unit 2 and at the individual processing units 5, measures are taken to
30 minimise image flickering.

According to the invention, the line frequency is raised to this end in the general processing unit 2 in order to eliminate what is called the interline flicker. It will be
35 raised for example from 15 kHz to 32 kHz.

However, in the individual processing units 5, one or several individual adjustments are made which make sure that every display unit 4 operates frequency-independent
5 vertically and horizontally. This adjustment consists for example in realising an automatic pulse width adjustment and/or in carrying out a frequency raise to eliminate what is called surface flicker.

10 The pulse width adjustment offers the advantage that one can for example automatically switch from a 50 Hz system to a 60 Hz system without any discontinuities being perceived in the displayed image. The automatic pulse width adjustment is preferably carried out by creating free
15 spaces in between the pulses, whose interval is adjusted such that the entire signal becomes totally continuous.

The frequency is raised from for example 50/60 Hz to at least 100 Hz and better still to 400 Hz.

20

According to yet another aspect of the invention, a distributed signal processing of the signals determining the image geometry is provided for.

25 In order to obtain a certain image geometry, control signals 13 are hereby transmitted to the individual processing units 5 which indicate which part of the image should be displayed at the display unit 4 concerned, whereby the individual processing units 5 then collect data
30 from the data stream 11, process them and display them, as a function of said control signals 13.

An example thereof is represented in figure 7, whereby the entire image which is normally displayed in the rectangle
35 defined by the entire surface of the display 3, is

compressed into a triangle 18. The image B1 of the picture line 19 must hereby no longer be displayed over the distance X, but over the short distance Y. In this case, the display units 4A and 4B will not be ordered to collect data from the data stream 11 via the communication protocol which is contained in the control signals 13, whereas the display unit 4C will be ordered to collect all the image information of the image B1 from the data stream 11, and to display this image B1, of the picture line 19, over the distance Y. The general processing unit 2 hereby only gives a command, whereas the recalculation for the display of the image B1 over the distance Y is carried out in the processing unit 5 of the display unit 4C.

According to another aspect of the invention, a dynamic image stabilisation is provided for.

To this end, one or several of the following techniques are preferably used:

20

- a time-dependant image stabilisation, whereby it is verified for pixels of the image how alterations in time occur between successive images, and whereby an image stabilisation effect is provided for before the images are displayed, for example by ignoring or attenuating brief alterations;
- a frequency-dependant image stabilisation, whereby it is verified how alterations occur in pixels of the image situated next to one another, and whereby an image stabilisation effect is provided for before the images are displayed;
- an amplitude-dependant image stabilisation;
- an image stabilisation as a function of the entire image content.

Such an image stabilisation can be realised either exclusively at the general processing unit 2 or exclusively at the individual processing units 5, but also distributed
5 over both.

It should be noted that the improvement of the image display by means of such a dynamic image stabilisation can also be applied in other display units 1 than those
10 described above, namely also in display units which are not assembled from different display units 4 and which do not necessarily have to be of the LED type. Hence, as far as the dynamic image stabilisation is concerned, the invention is not restricted to the above-described display device 1,
15 and it also extends to other display devices, including CRT projectors, picture tubes, etc.

According to a special characteristic of the invention, both the signals of the data stream 11 and the control
20 signals 13 are successively displayed from one display unit 4 to the next, and a number of, preferably each of the individual processing units 5 is provided with a master clock correction. This implies that all the signals, at each transition to a subsequent display unit 4, are again
25 optimally adjusted to one another, so that possible transmission errors are excluded, if not minimised.

In practice, different signals are preferably used for the basic colours red/green/blue (RGB signals), and possible
30 transmission errors in these RGB signals are minimised thanks to the above-mentioned master clock correction, in particular a cumulation of shifts and errors resulting from what is called jitter is counteracted at the master clock.

Such a master clock correction is preferably carried out by means of a proprietary crystal clock in each of the individual processing units 5.

5 Practically, the LED's 9 are driven by means of an uninterrupted current during normal operation, whereby the length of time for which the current is switched on is used as a control parameter. Moreover, in order to adjust the brightness and contrast, the value of the above-mentioned
10 current can be altered.

It is clear that the general processing unit 2 and the individual processing units 5 are equipped with the necessary electronic circuits in order to process the data
15 as described above, in other words to realise the above-mentioned means 10, 12 and 14. Any craftsman can derive from the above-described operations how these circuits should be built.

20 It should be noted that the display device 1 preferably also contains means to automatically recognise the position of a display unit 4 in the total image surface. These means consist for example in that, when the processing unit 2 is switched on, it assigns the address '1' to the first
25 display unit 4 coupled in series, the address '2' to the second one, and so on. In case of a systematic 'through' coupling as represented in figure 1, and when the number of display units 4 are put in per row, as well as the number of rows of display units 4 among themselves, the processing
30 unit 2 will automatically determine the position of each display unit 4 in the total display 3.

The invention is by no means limited to the above-described embodiment represented in the accompanying drawings; on the
35 contrary, such a method for displaying images on a display

device, as well as the device used to this end, can be made in all sorts of variants while still remaining within the scope of the invention.

Claims.

- 5 1. Method for displaying images on a display device, characterised in that use is made of a display device (1) comprising at least a general processing unit (2), a display (3) consisting of several display units (4) and an individual processing unit (5) per display unit (4),
10 whereby, in order to display the images, data concerning the image to be displayed are transmitted from the general processing unit (2) to the individual processing units (5) in the form of a data stream (11), in that there is a control communication between the general processing unit
15 (2) and each of the individual processing units (5) in the form of control signals (13), and in that data from the data stream (11) are collected at every individual processing unit (5) as a function of the control signals (13) transmitted to the individual processing units (5).
- 20 2. Method according to claim 1, characterised in that use is made of display units (4) which are serially coupled.
3. Method according to claim 1 or 2, characterised in that
25 use is made of display units (4) consisting of LED panels.
4. Method according to claim 1, 2 or 3, characterised in that a distributed signal processing is provided for between the general processing unit (2) on the one hand and
30 the individual processing units (5) on the other hand.
5. Method according to claim 4, characterised in that a distributed signal processing is at least provided for the signals related to the colour rendering, in other words a

distributed colour processing, and/or related to the brightness and/or contrast.

5 6. Method according to claim 5, characterised in that one or several individual adjustments are made at the individual processing units (5) related to one or several of the following possibilities:

- adjustment of the colour co-ordinates;
- 10 - adjustment of the brightness;
- adjustment of the contrast, in particular by means of what is called 'dynamic sample weight distribution';
- corrective adjustment as a function of the
- 15 temperature and/or age of the display unit (4);
- adjustment of the transfer functions RGB (red, yellow, blue);
- enlargement of the incoming video signal in the horizontal and/or vertical direction.

20

7. Method according to claim 6, characterised in that, in order to adjust the contrast, different modes are applied, whereby the linear connection between the input signal and the output signal is adjusted towards a non-linear

25 connection, in each individual processing unit (5), as a function of the command which is given via the control signals (13).

8. Method according to claim 5, 6 or 7, characterised in

30 that one or several individual adjustments are made at the general processing unit (2) related to one or several of the following possibilities:

- image stabilisation and/or noise suppression;

- tracking of the illumination of the image, in other words 'luminance tracking', whereby certain values of the luminance are included;
- histogram equalisation as a function of the entire
5 image to be displayed;
- observing of what is called cue flash and acting appropriately in case of such a cue flash;
- reduction of the image in relation to the original
10 input image in the horizontal and/or vertical direction.

9. Method according to any of claims 4 to 8, characterised in that a distributed signal processing is at least provided for the signals related to the image display, in
15 other words a distributed image processing.

10. Method according to claim 9, characterised in that a distributed signal processing is provided for which makes sure that, both at the general processing unit (2) and at
20 the individual processing units (5), measures are taken to minimise image flickering.

11. Method according to claim 9 or 10, characterised in that in the individual processing units (5), one or several
25 individual adjustments are made which make sure that every display unit (4) operates frequency-independent vertically and horizontally.

12. Method according to claim 9, 10 or 11, characterised in
30 that an automatic pulse width adjustment is realised in the individual processing units (2).

13. Method according to any of claims 9 to 12, characterised in that a frequency raise is carried out in

the individual processing units (5) to eliminate what is called surface flicker.

14. Method according to any of claims 9 to 13,
5 characterised in that the line frequency is raised in the general processing unit (2) in order to eliminate what is called the interline flicker and in order to obtain a higher image resolution.

10 15. Method according to any of claims 9 to 14, characterised in that a distributed signal processing is at least provided for the signals which determine the image geometry.

15 16. Method according claim 15, characterised in that, in order to obtain a certain image geometry, control signals (13) are transmitted to the individual processing units (5) which indicate which part of the image should be displayed at the display unit (4) concerned, whereby the individual
20 processing units (5) then collect data from the data stream (11), process them and display them, as a function of said control signals (13).

17. Method according to any of the preceding claims,
25 characterised in that it also provides for a dynamic image stabilisation.

18. Method according to claim 17, characterised in that at least one or several of the following techniques are
30 applied for the dynamic image stabilisation:

- a time-dependant image stabilisation, whereby it is verified for pixels of the image how alterations in time occur between successive images, and whereby an

image stabilisation effect is provided for before the images are displayed;

- a frequency-dependant image stabilisation, whereby it is verified how alterations occur in pixels of the image situated next to one another, and whereby an image stabilisation effect is provided for before the images are displayed;
- an amplitude-dependant image stabilisation;
- an image stabilisation as a function of the entire image content.

19. Method according to any of the preceding claims, characterised in that a number of the individual processing units (5), and preferably all of them, are provided with a master clock correction.

20. Method according to claim 19, characterised in that different signals are used for the basic colours red/green/blue (RGB signals), and in that possible transmission errors in these RGB signals are minimised thanks to the above-mentioned master clock correction.

21. Method according to any of the preceding claims, characterised in that use is made of LED's (9), and in that they are driven by means of an uninterrupted current during normal operation, whereby the length of time for which the current is switched on is used as a control parameter.

22. Method according to claim 21, characterised in that in order to adjust the brightness, and thus the contrast, the value of the above-mentioned current is altered.

23. Method for displaying images on a display device, whereby the data for forming the successive images are transformed in signals for a display (3), characterised in

that the image display is improved by evaluating the above-mentioned data and by applying a dynamic image stabilisation on the basis of this evaluation.

5 24. Method according to claim 23, characterised in that one or several of the following techniques are used for the dynamic image stabilisation:

- 10 - a time-dependant image stabilisation, whereby it is verified for pixels of the image how alterations in time occur between successive images, and whereby an image stabilisation effect is provided for before the images are displayed;
- 15 - a frequency-dependant image stabilisation, whereby it is verified how alterations occur in pixels of the image situated next to one another, and whereby an image stabilisation effect is provided for before the images are displayed;
- 20 - an amplitude-dependant image stabilisation;
- an image stabilisation as a function of the entire image content.

25 25. Display device for realising the method according to any of claims 1 to 22, characterised in that it comprises at least a general processing unit (2); a display (3) consisting of several display units (4); an individual processing unit (5) per display unit (4); means (10) which transmit at least data concerning the image to be displayed from the general processing unit (2) to the individual processing units (5) in the form of a data stream (11);
30 means (12) providing for a control communication between the general processing unit (2) and each of the individual processing units (5) in the form of control signals (13); and, per individual processing unit (5), means (14) which

collect data from the data stream (11) as a function of the transmitted control signals (13) for further processing and display.

- 5 26. Display device according to claim 25, characterised in that it is equipped with electronic circuits which make it possible to realise one or several of the steps 2 to 22 described in the claims.
- 10 27. Display device according to claim 25 or 26, characterised in that it has a modular design whereby the display units (4) are made in the form of replaceable tiles.
- 15 28. Display device according to claim 27, characterised in that it contains means which automatically recognise the position of a display unit (4) in the total image surface of the display (3).

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☒ FADED TEXT OR DRAWING
- ☒ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☒ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☒ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
